Introduction

Problem statement

Development of a control scheme in case of **rotor failure**, to allow the quadrotor to land with only three actuators.

Full control of attitude is lost: renounce the yaw angle control, maintaining flight control of a spinning vehicle

Double-loop architecture

- *Outer Control*

Yaw velocity is computed instead of the yaw angle

- *Inner Control*

Roll angle, pitch angle and yaw velocity regulated via feedback linearization

Quadrotor Model

Control Model

- Symmetric
- Rigid propellers
- Linear drag

Two reference frames:

- Earth frame: $\{R\}\{O, x, y, z\}$
- Body-fixed frame: $\{R_b\}\{O_b, x_b, y_b, z_b\}$

Rotations along roll (ϕ) and pitch (θ) angles are constrained:

$$\left(-\frac{\pi}{2} < \phi < \frac{\pi}{2}\right), \quad \left(-\frac{\pi}{2} < \theta < \frac{\pi}{2}\right)$$

while yaw angle ψ is unconstrained.

Inertia matrix in the body frame:

$$\mathbf{I} = \begin{bmatrix} I_{xx} & 0 & 0 \\ 0 & I_{yy} & 0 \\ 0 & 0 & I_{zz} \end{bmatrix}$$

where $I_{xx} = I_{yy}$ due to symmetry.

Control Model

Dynamic model, defined from generalized forces, drag force and weight:

$$\left\{ \begin{array}{l} \ddot{x} = \frac{1}{m}[(C_\phi S_\theta C_\psi + S_\phi S_\psi)u_f - k_t \dot{x}] \\ \ddot{y} = \frac{1}{m}[(C_\phi S_\theta S_\psi - S_\phi C_\psi)u_f - k_t \dot{y}] \\ \ddot{z} = \frac{1}{m}[(C_\phi C_\theta)u_f - mg - k_t \dot{z}] \\ \dot{p} = \frac{1}{I_{xx}}[-k_r p - qr(I_{zz} - I_{yy}) + \tau_p] \\ \dot{q} = \frac{1}{I_{yy}}[-k_r q - pr(I_{xx} - I_{zz}) + \tau_q] \\ \dot{r} = \frac{1}{I_{zz}}[-k_r r - pq(I_{yy} - I_{xx}) + \tau_r] \\ \dot{\phi} = p + qS_\phi T_\theta + rC_\phi T_\theta \\ \dot{\theta} = qC_\phi - rS_\phi \\ \dot{\psi} = \frac{1}{C_\theta}[qS_\phi + rC_\phi] \end{array} \right.$$

- k_r, k_t = rotational and linear drags, $N \cdot m \cdot s$;
- u_f = total upward lift force, N ;
- τ_p, τ_q, τ_r = torque around roll, pitch and yaw axis, $N \cdot m$;

Control Model

System inputs:

Generalized forces $u_f, \tau_p, \tau_q, \tau_r$

Real actuation:

Four motors forces f_1, f_2, f_3, f_4

Relation between these is given by:

$$\begin{bmatrix} u_f \\ \tau_p \\ \tau_q \\ \tau_r \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & -l & 0 & l \\ -l & 0 & l & 0 \\ d & -d & d & -d \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \end{bmatrix} \quad (1)$$

where

- d = ration between drag and thrust coefficient of the rotor, m
- l = arm length, m

Control Architecture

Control scheme

Figure 1: The double loop architecture in case of actuator loss.

In case of failure of rotor \mathcal{M}_2 the mapping (1) is:

$$\begin{bmatrix} u_f \\ \tau_q \\ \tau_r \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ -l & l & 0 \\ d & d & -d \end{bmatrix} \begin{bmatrix} f_1 \\ f_3 \\ f_4 \end{bmatrix} \quad (2)$$

and the neglected input is $\tau_p = l \cdot f_4$

In case of failure of rotor \mathcal{M}_2 the mapping (1) is:

$$\begin{bmatrix} u_f \\ \tau_q \\ \tau_r \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ -l & l & 0 \\ d & d & -d \end{bmatrix} \begin{bmatrix} f_1 \\ f_3 \\ f_4 \end{bmatrix} \quad (2)$$

and the neglected input is $\tau_p = l \cdot f_4$

The inverse of (2) is:

$$\begin{bmatrix} f_1 \\ f_3 \\ f_4 \end{bmatrix} = \frac{1}{4} \begin{bmatrix} 1 & -2/l & l/d \\ 1 & 2/l & l/d \\ 2 & 0 & -2/d \end{bmatrix} \begin{bmatrix} u_f \\ \tau_q \\ \tau_r \end{bmatrix} \quad (3)$$

State vector

$$\begin{aligned}\mathbf{x} &= [x_1 \quad x_2 \quad x_3 \quad x_4 \quad x_5 \quad x_6 \quad x_7 \quad x_8 \quad x_9 \quad x_{10} \quad x_{11} \quad x_{12}]^T \\ &= [\phi \quad \theta \quad \psi \quad p \quad q \quad r \quad x \quad y \quad z \quad \dot{x} \quad \dot{y} \quad \dot{z}]^T\end{aligned}$$

Input vector

$$\mathbf{u} = [u_1 \quad u_2 \quad u_3]^T = [u_f \quad \tau_q \quad \tau_r]^T \quad (4)$$

The neglected input is expressed as:

$$\tau_p = \frac{I}{2} \left(u_1 - \frac{u_3}{d} \right) \quad (5)$$

State-space model

$$\left\{ \begin{array}{l} \dot{\phi} = \dot{x}_1 = x_4 + x_5 S_{x_1} T_{x_2} + x_6 C_{x_1} T_{x_2} \\ \dot{\theta} = \dot{x}_2 = x_5 C_{x_1} \\ \dot{\psi} = \dot{x}_3 = \frac{1}{C_{x_2}} [x_5 S_{x_1} + x_6 C_{x_1}] \\ \dot{p} = \dot{x}_4 = \frac{1}{I_{xx}} [-k_r x_4 - x_5 x_6 (I_{zz} - I_{xx}) + \frac{1}{2} (u_1 - \frac{u_3}{d})] \\ \dot{q} = \dot{x}_5 = \frac{1}{I_{xx}} [-k_r x_4 - x_5 x_6 (I_{zz} - I_{xx}) + u_2] \\ \dot{r} = \dot{x}_6 = \frac{1}{I_{xx}} (-k_r x_6 + u_3) \\ \dot{x} = \dot{x}_7 = x_{10} \\ \dot{y} = \dot{x}_8 = x_{11} \\ \dot{z} = \dot{x}_9 = x_{12} \\ \ddot{x} = \dot{x}_{10} = \frac{C_{x_1} S_{x_2} C_{x_3} + S_{x_1} S_{x_3}}{m} u_1 - \frac{k_t}{m} x_{10} \\ \ddot{y} = \dot{x}_{11} = \frac{C_{x_1} S_{x_2} S_{x_3} - S_{x_1} C_{x_3}}{m} u_1 - \frac{k_t}{m} x_{11} \\ \ddot{z} = \dot{x}_{12} = \frac{1}{m} [u_1 C_{x_1} C_{x_2} - k_t x_{12} - mg] \end{array} \right. \quad (6)$$

Outer control loop

Outer control loop

The horizontal motion depends on the projection of the thrust vector on the (x, y) plane.

The direction of this vector depends on the roll and pitch angles.

Task of the Outer control:

Generate the right values of:

- roll and pitch angles to reach a desired horizontal position;
- yaw velocity to control vertical dynamics.

Outer control loop

Assuming the inner control loop stabilizes the state near the equilibrium:

$$x_1 = \phi \rightarrow \phi_d, \quad x_2 = \theta \rightarrow \theta_d, \quad x_6 = r \rightarrow r_d \quad (7)$$

Inputs at the steady-state are:

$$u_2 \rightarrow 0$$

$$u_3 \rightarrow x_{6d} k_r$$

$$u_1 \rightarrow \frac{u_3}{d} = \frac{x_{6d} k_r}{d}$$

Outer control loop

Rewrite the equations relative to (x, y, z) dynamics of (6) using:

1. assumption of small angles for ϕ_d and θ_d
2. inputs written at the steady-state
3. *new* state for outer control loop:

$$\begin{aligned}\tilde{x} &= [\tilde{x}_1 \quad \tilde{x}_2 \quad \tilde{x}_3 \quad \tilde{x}_4 \quad \tilde{x}_5 \quad \tilde{x}_6]^T \\ &= [x_7 \quad x_8 \quad x_9 \quad x_{10} \quad x_{11} \quad x_{12}]^T\end{aligned}$$

4. *new* control inputs vector:

$$\tilde{u} = [\tilde{u}_1 \quad \tilde{u}_2 \quad \tilde{u}_3] = \left[\frac{k_r x_{6d}}{dm} x_{1d} \quad \frac{k_r x_{6d}}{dm} x_{2d} \quad \frac{k_r x_{6d}}{dm} \right] \quad (8)$$

Outer control loop model:

$$\dot{\tilde{x}}_1 = \tilde{x}_4$$

$$\dot{\tilde{x}}_2 = \tilde{x}_5$$

$$\dot{\tilde{x}}_3 = \tilde{x}_6$$

$$\dot{\tilde{x}}_4 = C_\psi \tilde{u}_2 + S_\psi \tilde{u}_1 - \frac{k_t}{m} \tilde{x}_4$$

$$\dot{\tilde{x}}_5 = S_\psi \tilde{u}_2 - C_\psi \tilde{u}_1 - \frac{k_t}{m} \tilde{x}_5$$

$$\dot{\tilde{x}}_6 = \tilde{u}_3 - \frac{k_t}{m} \tilde{x}_6 - g$$

Outer control loop model:

$$\dot{\tilde{x}}_1 = \tilde{x}_4$$

$$\dot{\tilde{x}}_2 = \tilde{x}_5$$

$$\dot{\tilde{x}}_3 = \tilde{x}_6$$

$$\dot{\tilde{x}}_4 = C_\psi \tilde{u}_2 + S_\psi \tilde{u}_1 - \frac{k_t}{m} \tilde{x}_4$$

$$\dot{\tilde{x}}_5 = S_\psi \tilde{u}_2 - C_\psi \tilde{u}_1 - \frac{k_t}{m} \tilde{x}_5$$

$$\dot{\tilde{x}}_6 = \tilde{u}_3 - \frac{k_t}{m} \tilde{x}_6 - g$$

Not yet linear!

To linearize the nonlinear dynamics we manipulate the control inputs:

$$\begin{bmatrix} \tilde{u}_1 \\ \tilde{u}_2 \end{bmatrix} = \begin{bmatrix} S_\psi & -C_\psi \\ C_\psi & S_\psi \end{bmatrix} \begin{bmatrix} \tilde{\tilde{u}}_1 \\ \tilde{\tilde{u}}_2 \end{bmatrix} \quad (9)$$

Obtaining:

$$\begin{aligned} \dot{\tilde{x}}_4 &= \tilde{u}_1 - \frac{k_t}{m} \tilde{x}_4 \\ \dot{\tilde{x}}_5 &= \tilde{u}_2 - \frac{k_t}{m} \tilde{x}_5 \\ \dot{\tilde{x}}_6 &= \tilde{u}_3 - \frac{k_t}{m} \tilde{x}_6 - g \end{aligned}$$

Outer control loop

To linearize the nonlinear dynamics we manipulate the control inputs:

$$\begin{bmatrix} \tilde{u}_1 \\ \tilde{u}_2 \end{bmatrix} = \begin{bmatrix} S_\psi & -C_\psi \\ C_\psi & S_\psi \end{bmatrix} \begin{bmatrix} \tilde{\tilde{u}}_1 \\ \tilde{\tilde{u}}_2 \end{bmatrix} \quad (9)$$

Obtaining:

$$\begin{aligned} \dot{\tilde{x}}_4 &= \tilde{\tilde{u}}_1 - \frac{k_t}{m} \tilde{x}_4 \\ \dot{\tilde{x}}_5 &= \tilde{\tilde{u}}_2 - \frac{k_t}{m} \tilde{x}_5 \\ \dot{\tilde{x}}_6 &= \tilde{u}_3 - \frac{k_t}{m} \tilde{x}_6 - g \end{aligned}$$

Linear and decoupled

The control inputs are chosen as:

$$u_i = \ddot{x}_i + 2\xi_{out}c_{out}\dot{e}_i + c_{out}^2e_i \quad (10)$$

where:

- \ddot{x}_i is the feed-forward term;
- $e_i = x_{di} - x_i$ is the error;
- c_{out} represents the natural frequency of the system and must be small: we want the outer loop control to be slower than inner control loop;
- ξ_{out} represents the damping of the system.

Inner control loop

Task of Inner control loop:

to control the dynamics of the attitude angle and the yaw velocity.

Equation relative to ψ, θ, p, q, r expressed such that the origin of the system is an equilibrium point when the inputs are equal to zero.

State vector:

$$\hat{x} = \begin{bmatrix} \hat{x}_1 & \hat{x}_2 & \hat{x}_3 & \hat{x}_4 & \hat{x}_5 \end{bmatrix} = \begin{bmatrix} x_1 & x_1 & x_2 & x_3 & x_4 & (x_6 - \frac{mgd}{k_r}) \end{bmatrix} \quad (11)$$

Inputs vector:

$$\hat{u} = \begin{bmatrix} \hat{u}_1 & \hat{u}_2 & \hat{u}_3 \end{bmatrix} = \begin{bmatrix} (u_1 - mg) & u_2 & (u_3 - mgd) \end{bmatrix} \quad (12)$$

The system is described by:

$$\dot{\hat{x}} = \hat{f}(\hat{x}) + \hat{G}(\hat{x}) \hat{u} \quad (13)$$

$$\hat{y} = [\hat{h}_1 \quad \hat{h}_2 \quad \hat{h}_3] = [\hat{x}_1 \quad \hat{x}_2 \quad \hat{x}_5] \quad (14)$$

where:

$$\hat{f}(\hat{x}) = \begin{bmatrix} \hat{x}_3 + \hat{x}_4 S_{\hat{x}_1} T_{\hat{x}_2} + (\hat{x}_5 + \frac{mgd}{k_r}) C_{\hat{x}_1} T_{\hat{x}_2} \\ \hat{x}_4 C_{\hat{x}_1} - (\hat{x}_5 + \frac{mgd}{k_r}) s_{\hat{x}_1} \\ \frac{1}{I_{xx}} [-k_r \hat{x}_3 - \hat{x}_4 (\hat{x}_5 + \frac{mgd}{k_r}) (I_{zz} - I_{yy})] \\ \frac{1}{I_{yy}} [-k_r \hat{x}_4 - \hat{x}_3 (\hat{x}_5 + \frac{mgd}{k_r}) (I_{xx} - I_{zz})] \\ \frac{1}{I_{zz}} (-k_r \hat{x}_5) \end{bmatrix} \quad \hat{G}(\hat{x}) = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ \frac{I}{2I_{xx}} & 0 & -\frac{I}{2I_{xx}} \\ 0 & \frac{1}{I_{xx}} & 0 \\ 0 & 0 & \frac{1}{I_{zz}} \end{bmatrix}$$

The system fulfills the conditions for the feedback linearization:

- the sum of the relative degrees is equal to the dimension of the state vector;
- the decoupling matrix:

$$M(\hat{x}) = \begin{bmatrix} \frac{I}{2I_{xx}} & \frac{S_{\hat{x}_1} T_{\hat{x}_2}}{I_{xx}} & \frac{C_{\hat{x}_1} T_{\hat{x}_2}}{I_{zz}} - \frac{I}{2dI_{xx}} \\ 0 & \frac{C_{\hat{x}_1}}{I_{xx}} & -\frac{S_{\hat{x}_1}}{I_{zz}} \\ 0 & 0 & \frac{1}{I_{zz}} \end{bmatrix} \quad (15)$$

is always invertible.

Feedback Linearization

The system fulfills the conditions for the feedback linearization:

- the sum of the relative degrees is equal to the dimension of the state vector;
- the decoupling matrix:

$$M(\hat{x}) = \begin{bmatrix} \frac{I}{2I_{xx}} & \frac{S_{\hat{x}_1} T_{\hat{x}_2}}{I_{xx}} & \frac{C_{\hat{x}_1} T_{\hat{x}_2}}{I_{zz}} - \frac{I}{2dI_{xx}} \\ 0 & \frac{C_{\hat{x}_1}}{I_{xx}} & -\frac{S_{\hat{x}_1}}{I_{zz}} \\ 0 & 0 & \frac{1}{I_{zz}} \end{bmatrix} \quad (15)$$

is always invertible.

We can compute the linearizing input as:

$$u(x, v) = \alpha(x) + \beta(x) \cdot v \quad (16)$$

The (16) leads to the canonical Brunowski form:

$$\dot{x}_c = A_c x_c + B_c v \quad (17)$$

$$A_c = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad B_c = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (18)$$

The linear input v is chosen to regulate the attitude angles and the yaw velocity to the desired values, coming from the *outer control loop*.

Simulations

Trajectory tracking of cubic polynomial trajectory with $t \in [0, T]$

Initial values:

Variable	Value	Description
$\tilde{x}_{1,0}$	2 m	x
$\tilde{x}_{2,0}$	3 m	y
$\tilde{x}_{3,0}$	4 m	z
$\tilde{x}_{4,0}$	0 m/s	\dot{x}
$\tilde{x}_{5,0}$	0 m/s	\dot{y}
$\tilde{x}_{6,0}$	0 m/s	\dot{z}

Final values:

Variable	Value
$\tilde{x}_{1,T}$	0 m
$\tilde{x}_{2,T}$	0 m
$\tilde{x}_{3,T}$	0 m
$\tilde{x}_{4,T}$	0 m/s
$\tilde{x}_{5,T}$	0 m/s
$\tilde{x}_{6,T}$	0 m/s

Outer loop: Tracking

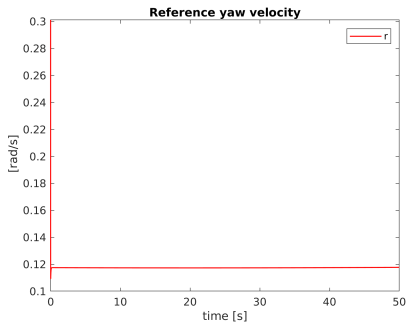

Trajectory tracking of cubic polynomial trajectory with $t \in [0, T]$

Outer loop: Tracking

Output of the outer loop:

$$y_1 = \phi, \quad y_2 = \theta, \quad y_3 = r$$

Inner loop: regulation

Initial values:

Variable	Value	Description
x_1	0 rad	ϕ
x_2	0 rad	θ
x_3	0 rad	ψ
x_4	0 rad/s	p
x_5	0 rad/s	q
x_6	mgd/k_r rad/s	r

Final values:

Variable	Value
x_1	$-\pi/4$ rad
x_2	$\pi/4$ rad
x_3	$\pi/4$ rad
x_4	-0.5 rad/s
x_5	0.5 rad/s
x_6	2.7 rad/s

Inner loop: Regulation

Inner loop: Regulation

Complete loop

Complete loop

Complete loop

Conclusions

Conclusions

Problem statement:

- Control a quadcopter in case of loss of one of the actuators

Proposed solution:

- Adopted strategy: **double loop** architecture
- Sacrificed state: yaw angle

Consequences:

- Horizontal position oscillates around the desired trajectory, allowing only slow recovering maneuvers

Issues:

- Motors force saturation, considered as uncertainty in the model
